

CHAPTER 09 FIBER OPTIC SENSORS INTRODUCTION: After the invention of LASER in 1960 a new branch in fiber optics developed in parallel with the communication which is also a well known and ...

The light is conducted to the receiver of the optical proximity sensor via the receiving fibre-optic cable. The fibre-optic cables can be cut to the desired lengths (e.g. with a cutter or a scalpel). In order to ...

Additional optical fibers have been produced, including plastic optical fibers, glass optical fibers with plastic claddings, photonic crystal (holey) optical fibers, doped active optical fibers, and others.

Because the detecting distances range from a couple inches to several meters, adjustment during installation is incredibly easy. Detection is possible even for small targets. Retro-reflective models ...

Do you have trouble adjusting the sensitivity for applications where a workpiece that is narrower than the optical axis diameter continuously passes through the light beam? In such a case, fully automatic ...

When using an OL10034x series amplifier, it is possible to set four different response speeds. The light intensity of the transmitter LED changes with the response speeds. This in turn results in a change to ...

These Fiber Units offer better detection of small objects at close distances (of 2 mm or less) than Standard Reflective Fiber Units. They also detect glossy surfaces more reliably than Standard ...

Solves thru-beam sensing tasks where the material is dense for container contents sensing, where the lens is subject to contamination build-up, or for long-range sensing in harsh environments.

Of course, using a fiber-optic also allows the sensor to be remote from the point of sensing, and allow physical adjustment of the sensor parameters as needed for the application.

There are two significant drawbacks to traditional thru-beams sensors: their two-piece architecture, and their need for accurate, stable alignment. A conventional thru-beam system requires a separate ...
